Introduction

Mechatronic linear servo systems are integral components in modern automation and robotics, combining principles of mechanics, electronics, and computing to achieve precise motion control. These systems are designed to convert electrical signals into linear motion, providing accuracy, speed, and repeatability in applications ranging from industrial machinery to medical devices.

At the heart of a mechatronic linear servo system lies the servo motor, which drives a linear actuator to produce controlled movement along a straight path. This is achieved through a combination of feedback loops, sensors, and controllers, allowing the system to adapt to dynamic conditions and maintain performance. The integration of advanced software algorithms further enhances their versatility, enabling applications such as pick-and-place operations, CNC machining, and adaptive manufacturing.

The development of mechatronic linear servo systems is a testament to interdisciplinary engineering, as it relies on innovations in material science, control theory, and embedded systems. Their growing adoption is driven by the demand for automation solutions that offer both precision and reliability, ensuring efficiency in complex and repetitive tasks across various industries.

By leveraging the synergy of mechanical design and electronic intelligence, mechatronic linear servo systems exemplify the capabilities of modern engineering in shaping the future of automation and control systems.

Methodology

Workflow:

Mechanical Design:

- 1) SG555123000\10K DC motor with encoder.
- 2) 1 m 20*20 V-slot aluminum extrusion bar.
- 3) Mini-V gantry Plate.
- 4) Idler pulley plate.
- 5) Motor mount plate.
- 6) Mini V- wheel bearing kit.
- 7) Timing pulley GT2.
- 8) GT2 timing belt.
- 9) Smooth idler pulley kit.

Circuit Connection:

Encoder:

VCC-> +5v on motor driver L298

GND-> GND on motor driver L298

Channel A-> Arduino pin 2

Channel B-> Arduino pin 3

Motor:

M+-> Connected to OUT 1 on motor driver L298

M--> Connected to OUT 2 on motor driver L298

Arduino:

Pin 2-> encoder A

pin 3-> encoder B

pin 8-> IN1 on motor driver

pin 9-> IN2 on motor driver

pin 10-> ENA on motor driver

GND-> GND on motor driver

Simulink Model:

Data Collection:

We calculated the PPR by dividing the pulses over revolutions for sample time = 50 sec, we made several trials and we got PPR = 360

We got R_a by resisting the motion of the motor and stopping it where $I=2.6$ A and $V=12$ Volts thus $R_a = V/I = 12/2.6=4.62$ Ohm

Before parameter estimation and tuning:

The data is documented in the attached excel sheet.

As shown in the velocity curve:

the settling time = 2 sec

thus $\tau = 2/4 = 0.5$

thus $K_i/K_p = 0.5$

Parameter Estimation:

We estimated the equivalent viscous friction, armature resistance, back emf constant, armature inductance, and equivalent moment of inertia.

J = equivalent moment of inertia

K_{bh} = back emf constant

b = equivalent viscous friction

L_a = armature inductance

R_a = armature resistance

DC motor model:

```

1 - Ra = 5;
2 - k_bh = 0.3;
3 - b = 0.01;
4 - Ia = 0.1 ;
5 - J = 0.1;

```

We compared the experimental data for velocity and PWM for 3 sec time showed in the .mat file and excel sheet file with the simulation data and made parameter estimation as follows:

Estimation Progress Report			
Iteration	F-count	Exp (Minimize)	
0	11	432.5197	
1	22	370.2485	
2	33	44.2998	
3	44	11.5087	
4	55	10.5603	
5	66	3.6624	
6	77	0.3973	
7	88	0.1025	

Cascaded PID Tuning

Velocity loop:

Block Parameters: PID Controller

Discrete-time

Sample time (-1 for inherited): 0.005

Integrator and Filter methods:

Compensator formula

$$P + I \cdot T_s \frac{1}{z-1} + D \frac{N}{1 + N \cdot T_s \frac{1}{z-1}}$$

Main Initialization Saturation Data Types State Attributes

Controller parameters

Source: internal

Proportional (P): 150

Integral (I): 300 ☐ Use I*Ts (optimal for codegen)

Derivative (D): 0 ☐ Use externally sourced derivative

Filter coefficient (N): 100 ☒ Use filtered derivative

Automated tuning

Model Response after tuning:

From the velocity response graph, the settling time is reduced from 2 sec to 0.42 sec and the position error becomes 2.5%, thus for 20 cm input, the cart moves 20.5 cm.

Discussion

This project had some issues summed up as follows: there were setup, control task, and parameter estimation issues.

Setup: there were wiring connections issues as many components were not working and it was hard to find the working jumpers, arduino, h-bridge and motor. Moreover, the motors were not working properly except for the one we used.

Tuning: direction block was not working so we reversed the direction of the cart.

Parameter estimation: ratio of $K_i/K_p = 41$ was not used for its purpose; instead, we used ratio 0.5 after several iterations for the best response.

Results

Controlling movement of the linear cart using cascaded PID the controller was able to effectively reduce the overshoot and settling time of the system, achieving a settling time of 0.42 seconds. These results indicate that the cascaded PID controller is an effective control strategy for movement control of linear carts, as it allows for precise and accurate positioning of the cart. The results of the experimental data showed that the linear cart was able to reach and maintain the desired position with a high degree of accuracy (error 2.5%).

Conclusion

We managed to successfully build a mechatronic linear servo system after correctly forming the setup, building the simulink model, initializing parameters, performing parameter estimation, making Cascaded PID tuning, and consequently the desired position was achieved accurately.
